## Motivation

There are many considerations that must be made when finding temporary housing, either for vacations or business trips. Airbnb is a popular website that allows individuals or businesses to list potential places for users to choose. These users can choose where they wish to stay based on location, accommodations, how many beds they need, and price. We sought to create a model that predicts the price of an Airbnb listing based on various variables.

Airbnb data has been scraped by a team of contributors and gathered on a website [here](#). Their motivation is to show transparency in how spaces are being rented to tourists in their communities.

When coming across this dataset, we found several missing values in the price of different Airbnb listings. Of the 36111 listings we found 14783 missing prices. We believe that we can use the latitude, longitude, beds, bathrooms, and neighborhood location among other variables to impute the missing pricing data for these listings.

## Dataset Description

### Price

#### Summary Statistics

price
Min. : 10.0
1st Qu.: 88.0
Median : 152.0
Mean : 234.5
3rd Qu.: 272.0
Max. : 10000.0
NA's : 14783

#### Distribution of Price

```
# A tibble: 10 x 2
  price     n
  <dbl> <int>
1 10000     3
2 9999      1
3 9895      1
4 9000      1
5 8758      2
6 8403      1
7 7500      1
8 7024      1
9 6112      2
10 6041     1
```
